Abstract

Background: One of the important therapeutic approaches in cancer field is development of compounds which can block the initial tumor growth and the progression of tumor metastasis with no side effects. Thus, the recent study was carried out to design anti-VEGFR2 peptidomimetics as the most significant factor of angiogenesis process and evaluate their biological activity by in vitro assays.

Methods: We designed anti-VEGFR2 peptidomimetics with anti-angiogenic activity, including compound P (lactam derivative) and compound T (indole derivative) by using in silico methods. Then, the inhibitory activity on angiogenesis was evaluated by using angiogenesis specific assays such as Human Umbilical Vein Endothelial Cell (HUVEC) proliferation, tube formation in Matrigel, MTT and Real-Time PCR. IC50 values of the compounds were also determined by cytotoxicity plot in MTT assay.

Results: Compounds P and T inhibited HUVEC cell proliferation and viability in a dose-dependent manner. The IC50 for compound T and compound P in HUVEC cell line were 113 and 115 μg/ml, respectively. Tube formation assay revealed that both compounds can inhibit angiogenesis effectively. The results of Real-Time PCR also showed these compounds are able to inhibit the expression of CD31 gene in HUVEC cell line.

Conclusion: Our study suggested that compounds P and T may act as therapeutic molecules, or lead compounds for development of angiogenesis inhibitors in VEGF-related diseases.

Introduction

Angiogenesis or development of blood vessels happens in physiological conditions such as wound healing. This process is resulted through coordination of different pro- and anti-angiogenic factors. In other words, the balance among these growth factors is missed in pathological conditions like rheumatoid arthritis, and especially cancers. Among these factors, Vascular Endothelial Growth Factor (VEGF) has gained a reputation for its outstanding role in angiogenesis. In fact, the interaction between VEGF and KDR (VEGF receptor-2) is considered as the most significant part in the process.

Several chemical or molecular approaches have been suggested for targeting VEGF-VEGF receptor interaction such as ATP mimetics, tyrosine kinase inhibitors, antibodies, peptides and receptor blocking agents. In the area of peptides, ST100 and LPPHSS have been identified as anti-VEGFR2 peptides. Furthermore, some peptides have been identified, which inhibit the binding of VEGF to its receptors in Human Umbilical Vein Endothelial Cells (HUVECs). Peptides are cost-effective and safe compared with monoclonal antibodies. Peptides have several advantages such as high penetration into tissues and increased bioavailability. However, these peptides are faced with some limitations such as high susceptibility to proteasomal degradation. As an alternative, pseudo peptides and modified peptides that are used as peptidomimetics. The resistance of peptidomimetics to proteasomal degradation is higher than peptides, which results in increase of peptidomimetics bioavailability. Thus, peptidomimetics are considered as suitable candidates for new generation of therapeutic compounds, which have a variety of advantages such as being water soluble.
designing anti-angiogenic peptidomimetics
non-immunogenic, increased selectivity, capability to
cross tissue barriers, decreased side effects and toxicity
compared with peptides 25.

Design of peptidomimetics and evaluation their bio-
ological activity have been reported by various research
groups. For instance, Moradi et al., designed antifungal
indole and pyrroline-2, 4-dione derivative peptido-
mimetic against Aspergillus niger, Candida albicans,
and Saccharomyces cerevisiae fungi. The authors ob-
served the structure C2 has a potent antifungal activity
and could be used as a template for designing anti-
fungal peptidomimetics.

Computation and bioinformatics has become a key
aspect of drug discovery and contributing to both target
discovery and validation. Bioinformatics will continue
to play an important role in response to the waves of
gene wide data sources- including Expressed Se-
quence Tags (ESTs), microbial genome sequences,
model organism sequences, polymorphisms, gene ex-
pression data and proteomics 26. However, such
knowledge sources must be integrated in future. The
bioinformatics tools can be used to discover the pep-
idomimetics 26,27. Among these tools, Super-Mimic
software identifies compounds that mimic parts of a
protein. In a short statement, Super-Mimic provides
libraries that contain peptidomimetic building blocks in
one hand and protein structures on the other hand. The
search for promising peptidomimetics for target pep-
tide is based on the superposition of the peptide with
several conformers of the mimetic. This search results
in a list of peptidomimetics, the position within the
protein where the mimetic could be inserted, and also
the conformation of the mimetic that fits the best 26.

Since, tumor growth, progression, and metastasis
are severely influenced by generation of pro-angi-
genic VEGF, promising anti-angiogenic drugs are im-
portant and currently available; however, their suscep-
tibilities to drug resistance and long term toxicity are
serious obstacles to their use. As a result, we require
the development of novel therapeutic approaches for
effective and safe angiogenic inhibitors. The current
study, was carried out to design anti-VEGFR peptide-
mimetics and evaluate their biological activity by
in vitro assays- such as tube formation, HUVEC prolif-
eration and the gene expression of
in vitro

Table 1. The result of multiple sequence alignment of anti-VEGFR2

alignments were carried out in order to find a better
homology among anti-VEGFR2 peptide sequences.
After sequence alignment, peptides with more homolo-
y in sequence were selected to extract the final pat-
terns among each group (Table 1). In the following,
peptidomimetic structures were designed based on the
final pattern obtained from sequence alignment using
T-coffee, in which, scores are based on colors; posi-
tions that have no consistency with the in-house pep-
tide library are in blue, a little in green, better positions
in red, and finally yellow. The Basic Local Alignment
Search Tool (BLAST) was used to discover final pat-
tern from sequences alignments.

Mimetic design
SuperMimic software provides a library of pepti-
domidimetic structures which have been arranged in
sub-libraries such as beta-turn or gamma-turn mimet-
ics. In this study, SuperMimic was used to replace
RKRKKSR with peptidomimetics structures which are
in SuperMimic library. Among designed peptidomi-
metics, two structures were selected with lower than
9x10^3 Â Root Mean Square Deviation (RMSD) of the
backbone atoms and more similarity in chemical nature
to the backbone and their side chains (Figure 1) 26.

Drug preparation and dilution
Compound P and compound T were purchased from
Jaber-ibn-Hayan and Sigma companies, respectively.
These two compounds were diluted in water and
DMEM medium at concentrations range of 25, 50, 100,
200, and 400 µg/ml.

Cells culture condition and reagents
Adherent cell line of HUVEC was provided from
Department of Cell Bank, Pasteur Institute of Iran. The
cells were cultured in media consisting Dulbecco’s

Materials and Methods

Collection of anti-angiogenesis peptides
In the current study, several anti-VEGFR2 peptides
were collected from previous studies (Table 1), and
their amino acid sequences were used as the input data
for sequence alignment and to identify the common
amino acid sequences among them 28-32.

Sequence alignments
T-Coffee V 5.13, multiple sequence alignment tool,
was employed for sequence alignment of anti-VEGFR2
peptides 33. In this way, the various sets of sequence
Modified Eagles Medium (DMEM; Invitrogen, Carlsbad, CA) with 10% Fetal Bovine Serum (FBS), penicillin (100 U/ml), and streptomycin (100 μg/ml) in 37°C at 5% CO₂. In the following, the cells were passaged using 0.25% trypsin, and the medium was refreshed every 3 days. Ascorbic acid (Vitamin C) was used as reference compound of angiogenesis inhibitor, in the following in vitro assays.

**MTT viability assay**

To evaluate the cytotoxicity of the compound P and compound T, MTT assay was utilized in this research. In MTT assay, HUVEC cell line was treated with increasing doses of compounds P and T. To achieve this goal, HUVEC, 10⁴ cells, were plated in 96-well flat-bottom plates and incubated for 24 h at 37°C. Then, 50 μl of these compounds were added to each well of HUVEC cell line at concentrations of 25, 50, and 100/μl. After 24 h treatment, the medium was replaced with 100 μl of MTT [3-(4, 5-dimethylthiazol-2-yl)-2, 5-diphenyltetrazolium bromide] and was incubated for 4 h in the dark conditions. After incubation, MTT solution was removed. Then, 100 μl of isopropanol was added to each well and sample was incubated for additional 30 min in the dark. In final, the reactive product was measured at 570 nm with a reference absorbance in 630 nm by using an ELISA reader (Oggunon Teknika, Netherlands). The experiments were repeated three times.

To obtain IC₅₀ for compound P and compound T, the cytotoxicity was calculated at different doses by the following formula:

\[
\text{Cytotoxicity} = 1 - \frac{\text{Mean absorbance of toxicant}}{\text{Mean absorbance of negative control}}
\]

In the following, Graphpad Instat software, version 3 was used to determine IC₅₀ for compound P and compound T.

**Capillary-like tube formation assay**

The in vitro tube formation assay was made to discover the VEGF neutralizing effects of compound P and compound T. In this assay, Matrigel was put at 4°C for overnight and then was diluted with equal volume of serum-free EBM-2 medium, for the final concentration of Matrigel as 5 mg/ml. Next, each well of 96-well plates were coated with 50 μl diluted Matrigel and were incubated at room temperature for 45 min. The starved HUVEC cells (1x10³ cells well⁻¹) were plated in EBM-2 medium supplemented with 0.1% charcoal-stripped FBS, and then were treated with peptidomimetics at IC₅₀ concentration (IC₅₀ for compound T and compound P was 113 and 115 μg/ml, respectively) in the presence or absence of VEGF (50 ng/ml). VEGF and PBS were utilized as positive and negative control, respectively. Tubular structures were imaged and counted after 12 h by Fluorescence microscopy (N800F model) under magnification 40X. The tube structures in turn were scored by sprout formation counting.

**Quantitative real-time PCR**

In the recent study, Quantitative Real-Time PCR was employed to determine whether the two compounds could inhibit the expression of CD31 gene (endothelial cell marker) in HUVEC cells or not. CD31 gene was selected because it was known as its expression is a marker of angiogenesis in HUVEC cells. Vitamin C and free angiogenesis inhibitor were used as the positive and negative controls. In this assay, total RNA extracted and purified by using RNeasy Plus mini kit (Qiagen, USA). The extracted RNA was diluted with 30 μl RNAse-free water and was quantified by spectrophotometer instrument (NanoDrop, Eppendorf, Germany). In the following, one-strand DNA was generated using Prime Script RT Reagent Kit (TaKaRa, Japan). Gene Runner v. 3.05, Primer Express v. 2.5 and Beacon Designer v. 7.5 were used to design CD31 gene primer. The primer sequences were included F: 5’-TCAAGGCTCAGCACAGA-3’ and R: 5’-GCAC TCTTCCCAACAC-3’. Real-Time PCR was conducted through SYBR Premix Ex Taq II master mix kit (TaKaRa, Japan) on a one-step instrument (Applied Bio systems, USA). Specific primers for GAPDH, as endogenous control, were included F: 5’-GAGTCAC TGCGTCTTTCA-3’ and R: 5’-TCTTGAAGCTGT GTCATACTTC-3’. The thermal conditions for amplification were 95°C for 15s as holding time, 95°C for 5s and 60°C for 30s in each cycle. Fluorescence was collected in annealing-extension time in each cycle. Melting curve analysis was carried out in three steps: 95°C, 60°C and stepwise heated to 95°C with a ramp rate of 0.3°C. In final, data was analyzed by using ΔΔCt method.

**Statistical analyses**

Graphpad Instat V3.00, was used for analyzing of data in MTT experiments. Comparison of groups was performed using t-test and one-way analysis of variance (ANOVA) by using SPSS V20.00. The results from the assays were expressed as the mean±SEM from three independent experiments. The level of statistical significance was set on 0.05.
Results

Collection of peptides and multiple sequence alignment

In the recent research, a total of 18 anti-VEGFR2 peptides were collected from previous studies (Table 1)\(^7,28\text{-}32\). Multiple sequence alignment revealed RKRKKSR as the final peptide pattern. As seen in Table 1, there are several arginine and lysine acid amines in this peptide pattern.

Peptidomimetics design

The final peptide pattern, RKRKKSR, was obtained from 18 anti-angiogenic peptides that indicated more sequence homology to each other with high score (Table 2). The mimetic design-mediated pattern was used in a similarity search tool, namely PubChem, to find structures close to it. Finally, a lactam derivative [(2S, 5R, 6R)-3, 3-dimethyl-7-oxo-6-[(2-phenylacetyl) amino]-4-thia-1-azabicyclo [3.2.0] heptane-2-carboxylic acid] and an indole derivative [(2S)-2-amino-3-(1H-indol-3-yl) propanoic acid], were selected and used as compound P and compound T in this study (Figure 1).

MTT assay

As shown in Figure 2, the viability of the cells decreased after exposure to both compounds in a dose-dependent manner. The IC\(_{50}\) values for compound T and compound P in HUVEC cell line were 113 and 115 \(\mu g/ml\), respectively. MTT assay showed a significant difference between T25 and control, T50 and control, T100 and control, P25 and control, P50 and control, as well as P100 and control. Dose response curves of MTT assay for compounds T and P, at different doses 25, 50, 100 \(\mu g/ml\) are presented in Figure 3.

Tube formation assay

As shown in Figure 3, a decrease in the sprout points and tube formation was observed in VEGF-treated HUVEC after treatments with both compounds (Figure 4A and B). Tube formation was dependent on VEGF, where a network of tubes with several sprout points was more obvious in the VEGF-treated HUVEC than the VEGF-non-treated HUVEC (Figure 4C). Significant effect was not observed for negative control (PBS without VEGF) (Figure 4D). As a result, it was revealed that both compounds can inhibit angiogenesis, effectively.

Real time PCR

Expression of \(CD31\) gene decreased dramatically at concentrations 50, 100, 200, 400 \(\mu g/ml\) of compound T in comparison to negative control (p<0.01), and positive control (p<0.05) (Figure 5, Table 2). Furthermore, it was observed a decrease in expression of \(CD31\) gene after treating cells with compound P in different doses, in comparison to negative and positive controls (p<0.01). However, significant difference was not observed among concentrations 50, 100, 200 \(\mu g/ml\) of compound P (Figure 5). Interestingly, there is a significant difference (p<0.01) between both compounds in different concentrations (50, 100, 200 \(\mu g/ml\)) (Figure 5). The melting curve of real-time PCR of \(CD31\) gene expres-
pression in the various concentrations of the two compounds P (A) and T (B) is presented in figure 6.

The results of Real-Time PCR showed that, in all concentrations, the inhibitory effect of T compound on the CD31 expression is greater than that of P compound. We achieved some interesting results experimentally. In different doses of P and T, the expression of CD31 gene decreased with increasing concentrations of both compounds. According to the statistical analysis, we conclude that T compound significantly reduced the expression of the CD31 gene compared with the control sample (C vitamin). Regarding these points, T compound is a more suitable candidate for angiogenesis control.

Discussion

In the cancer researches, VEGF is known as a key modulator for angiogenesis process. Thus, inhibiting the interaction VEGF and its receptor through antagonistic peptides is an effective and useful anti-angiogenic therapy. The studies on this item resulted in identification of important amino acids, which are involved in VEGF and its receptor interaction. Coupling this information with Alanine-scan analysis resulted in development of potent drug candidates with anti-angiogenic activity. Recently, researchers revealed the CPQPRPLC as a sequence targeting VEGFR1. In this way, the RPL shorter peptide was recognized as minimal sequence required for activity. In addition, it has been identified a peptide derived from VEGF gene, which involved in binding to HUVEC surface. This 20 amino acid peptide showed an inhibitory activity against cell migration and tumor growth in lung cancer.

In the current study, our efforts to design anti-angiogenic peptidomimetics resulted in finding two different compounds, namely P and T, by using in silico analysis. We first used MTT test to evaluate the cytotoxicity of the compounds. As a result of applying various concentrations of drugs, we detected 50% as 115 and 113 for compound P and compound T, respectively. We also conclude that these drug leads do not have a very toxic effect on HUVEC cells at certain doses. Therefore, these compounds can be considered as a treatment option, if they can inhibit target gene. In this regards, we used the results of this test to design real-time PCR. To do this test, according to real-time PCR analysis, it can be concluded that for concentrations above IC50 for compound T, there is no significant difference in inhibiting gene expression, because inhibition of gene expression has taken place completely in concentrations equal to or greater than IC50. By comparing the results of both compounds, we found that at all concentrations, T compound significantly reduced CD31 gene expression compared with P compound. Comparison of gene expression in three different concentrations of each drug with negative control sample also showed that there was a significant difference in all concentrations in comparison with negative control. Since toxicity of compound T is less, and also reduced CD31 gene expression more, T compound seems to be more suitable candidate for angiogenesis control in cancers conditions.

Similar to our study, a number of researches have also reported some successes on design of anti-angiogenic peptidomimetics. Foy et al, for instance, designed peptidomimetics against VEGF. The authors indicated that peptidomimetics discovered can induce anti-tumor responses in vitro and in vivo. Foy et al and Behelgard et al also demonstrated that the VEGF peptidomimetics can induce anti-angiogenic responses, effectively. Binétruy-Tournaire et al screened a phage epitope library by affinity for an anti-VEGF neutralizing monoclonal antibody, and isolated peptides binding KDR specifically. Among synthetic peptides, ATWLPPR totally abolished VEGF binding to cell-displayed KDR. In vitro, this effect resulted in
Designing Anti-Angiogenic Peptidomimetics

Figure 6. The melting curve of real-time PCR of CD31 gene expression in the various concentrations of the two compounds P (A) and T (B).

inhibition of VEGF-mediated proliferation of HUVECs in a dose-dependent manner, and endothelial cells in a type-specific manner. In vivo, ATWLPPR completely abolished VEGF-induced angiogenesis in rabbit model. As a result, the authors suggested ATWLPPR is an effective antagonist of VEGF binding, and this peptide can be a suitable inhibitor of tumor angiogenesis. In agreement with our findings, their results revealed that designing of anti-angiogenic peptidomimetics by using SuperMimic, and evaluation their biological activity by in vitro assays can be used to find inhibitors of tumor angiogenesis.

Vicari et al. designed peptides to mimic VEGF-binding site to its receptor VEGFR-2. The VEGF peptide mimic, VEGF-P3 (CYC), showed the highest affinity to VEGFR-2 by surface plasmon resonance assay. In addition, in several angiogenic in vitro assays, the authors observed that all VEGF mimics inhibited endothelial cell proliferation, migration, and network formation with the conformational VEGF-P3 (CYC) being the best. Similarly, their findings demonstrated that the structure-based design is important for development of anti-angiogenic peptidomimetics. Kim et al. also developed MAP2-dRK6 peptide with high anti-tumor and anti-VEGF activity. MAP2-dRK6 peptide was effective in many respects such as inhibition of VEGF binding to its receptors, VEGF-induced migration, ERK signaling of endothelial cells, and tube formation of endothelial cells. In addition, MAP2-dRK6 blocks growth of VEGF-secreting colorectal cancer cells in vivo by suppression of angiogenesis. In agreement with our findings, their results revealed that anti-angiogenic peptidomimetics can be used as lead compound or therapeutic molecule for development of drugs for VEGF-related angiogenic diseases.

Conclusion

Since, angiogenesis is severely influenced by pro-angiogenic VEGF, promising anti-angiogenic drugs are important and currently available; however, their susceptibilities to drug resistance and long term toxicity are serious obstacles to their use. As a result, we require the development of novel therapeutic approaches for effective and safe angiogenic inhibitors. We designed anti-VEGFR peptidomimetics and evaluated their biological activity by in vitro assays. Compounds P and T inhibited HUVEC cells proliferation and viability in a dose-dependent manner. The IC50 for compound T and compound P in HUVEC cell line was 113 and 115 μg/ml, respectively. Tube formation assay revealed that both compounds can inhibit angiogenesis effectively. The results of Real-Time PCR also showed these compounds are able to inhibit the expression of CD31 gene in HUVEC cell line. In summary, our results revealed that compound P (lactam derivative) and compound T (indole derivative) have anti-angiogenic activity and can be used for further studies in order to discovery and design anti-angiogenesis compounds.

Acknowledgement

I would like to express my gratitude to our cell bank lab supervisor, Mr Mohammad Majidi, who guided me throughout this project. I would also like to thank my family and friends who supported me and offered deep insight into the study.
